(Received: 02 September 2011; accepted: 09 October 2011)

Prolonged-release microcapsules of Ampicillin Hydrochloride (AH) were prepared by employing ethyl cellulose as a polymer in various ratios of 1:1, 1:3 & 1:4, by emulsion solvent diffusion technique. Scanning electron microscope photographs of samples revealed that all prepared microcapsules were almost spherical in shape and have a slightly smooth surface and evaluated for particle size, shape, flow properties, wall thickness, drug encapsulation efficiency and in vitro release performance. The drug carrier interactions were investigated in solid state by FT-IR spectroscopy. The present study concerned with the development and characterization of ampicillin microcapsules prepared by thermal change method using different ratios (1:1, 1:3 and 1:4) of ethyl cellulose in order to select the best microcapsule formulation with a good encapsulation efficiency and drug release profile. The obtained microcapsules were discrete, spherical with free flowing properties. The encapsulation efficiency was found to be in the range of 66.17-72.99%. The in vitro release profile of Ampicillin indicates that all the batches of microcapsules showed controlled and prolonged drug release over an extended period of 12 h. Drug release from the microcapsules (F1 and F2) was 56-51 % in first 6 hours, with the initial burst of nearly 50% within one hour. Drug release from microcapsules (F1 and F2) was 60-56% and sustained up to 8 h with initial burst of 50-54 % in first 6 h, resulted with increase in cross-linking time for 5-6 hours, Drug release from microcapsules (F2 and F3) sustained the drug release up-to 12 hours. The therapeutic effect of drugs that have a short biological half-life may be enhanced by formulating them as extended- or sustained-release dosage forms. Extended- and sustained-release dosage forms prolong the time that systemic drug levels are within the therapeutic range and, thus, reduce the number of doses the patient must take to maintain a therapeutic effect, thereby increasing compliance.

Key words: Microcapsules, Ampicillin, Ethyl cellulose, Sustain release.

The science of drug delivery may be described as the application of chemical and biological principles to control the in vivo temporal and spatial location of drug molecules for clinical benefit. When drugs are administered, only a very small fraction of the dose actually hits the relevant receptors or sites of action, and most of the dose is actually wasted either by being taken up into the “wrong” tissue, removed from the “right” tissue too quickly, or destroyed on route before arrival. Scientists researching drug delivery seek to address these issues in order to maximize drug activity and minimize side effects. Drug delivery is becoming an extremely demanding science. The reasons are essentially threefold: (a) the emergence of the more challenging low-molecular-weight molecules and bio macro molecules with either poor
aqueous solubility, poor tissue permeation, or both, 
(b) the increased use of biological materials with 
poorly understood physical properties or 
questionable shelf life issues, and (c) the 
realization that if the portion of the dose 
responsible for adverse events could be directed 
away from sites where they originate, toxic side 
effects would become less frequent, thus benefiting 
the therapeutic index3,4. Microencapsulation is a 
useful method which prolongs the duration of drug 
effect significantly and improves patient 
compliance.

Ampicillin, a potent antibiotic with 
relatively short-termed stability in aqueous 
solutions, is used clinically to treat a broad range 
of bacterial infections. This drug has a shorter 
biological half-life (1 hrs); it needs multiple 
administrations in injectables and oral dosage form, 
which often results in dose related side effects 
and poor patient compliance5. Therefore, ampicillin 
is an ideal candidate for sustained release 
formulation, resulting in more reproducible drug 
absorption and reducing the risk of local irritations 
compared to single dosage forms. The aim of 
present work was to prolonged-release 
microcapsules of Ampicillin Hydrochloride (AH) 
were prepared by employing ethyl cellulose as a 
polymer in various ratios of 1:1, 1:3 & 1:4, by 
emulsion solvent diffusion technique.

MATERIAL AND METHODS

Materials

Ampicillin (Zim Labs. Pvt. Ltd., Nagpur) 
was used as a water insoluble model drug with a 
very bitter taste. Ethyl cellulose (Lobachemie. Pvt. Ltd. Mumbai) dichloro methane (Loba chemie. Pvt. Ltd. Mumbai) acetone (Lobachemie. Pvt. Ltd., Mumbai), polyvinyl alcohol (Lobachemie. Pvt. Ltd., Mumbai) were used. All other Chemicals and solvents used were of analytical reagent grade.

Preparation of microspheres

All microspheres were obtained by the 
emulsion solvent diffusion method using distilled 
water as an external phase, in which 1% of PVA 
was dissolved as an emulsifier. The internal phase 
consisted of a good solvent and a bridging liquid 
involving ampicillin polymer. At first, the drug and 
polymer were co-dissolved in an organic solvent 
mixture that was composed of ethanol, acetone 
(good solvent) and dichloromethane (bridging 
liquid). The drug solution was slowly injected via 
a syringe into the external water phase (poor 
solvent) under agitating. The system was stirred 
continuously for about 1 hr. Along with the good 
solvent diffusing into the poor solvent, droplets 
gradually solidified and formed microspheres6.

Then, the system was filtered to separate 
the microspheres from the preparation system. The 
resultant product was washed with distilled water 
and dried in an oven at 40°C for 12 hr. the whole 
process was carried out at room temperature7.

Morphological and Topographical 
characterization

Microcapsules were observed with 
trinocular microscope (Lebo med ATC-2000, Japan) 
and scanning electron microscope (LEO, 435 VP, 
U.K.). Their diameters were determined with a pre-
calibrated graduated eyepiece. Particle size was 
calculated by using equation.

\[ X_g = 10 \times \left( \frac{\sum (n_i \times \log X_i)}{N} \right) \]

Where, \( X_g \) is geometric mean diameter, \( n_i \) 
is number of particles in range, \( X_i \) is the midpoint 
of range and \( N \) is the total number of particles8,9.

All the experimental units were scrutinized in 
triplicate (n=3).

Flow properties

Flow ability of microcapsules was 
investigated by determining angle of repose, bulk 
density,

Carr’s index and Hausner ratio. The angle 
of repose was determined by fixed funnel method. 
The microcapsules were tapped using bulk density 
apparatus (Electro lab tap density tester, (USP) 
ETP-1020) for 1000 taps in a cylinder and the 
change in volume was measured10-12.

Carr index and Hausner ratio were calculated by 
the formula:

\[ \text{Carr index} \% = \left( \frac{D_f - D_0}{D_0} \right) \times 100 \]

\[ \text{Hausner ratio} = \frac{D_f}{D_0} \]

Where, \( D_f \) is poured density; \( D_0 \) is tapped 
density. All the experimental units were studied in 
triplicate (n=3).

Drug content and encapsulation efficiency (DEE)

Accurately weighed microcapsules 
equivalent to 50 mg of ampicillin, were suspended 
in 100 mL of simulated gastric fluid (GF, phosphate 
buffer, pH 3.2) and kept for 24 h. Next day it was 
filtered after stirring and analyzed by using UV-
Visible spectrophotometer (Systronic PC Based
double beam Spectrophotometer-2201, Shimadzu, Japan) after suitable dilution at 320 nm. Drug entrapment efficiency (DEE) was calculated using the formula:\[\text{DEE} = \left( \frac{\text{Practical drug content}}{\text{Theoretical percent drug content}} \right) \times 100\]

Each sample was analyzed in triplicate (n=3).

**Wall thickness of microcapsules**

Wall thicknesses of the microcapsules were determined by the method suggested by Luu et al., using equation:\[h = r (1-P) d_1 D \left[3d_2 + (1-P) d_1\right]\]

Where, h is wall thickness; r is mean radius of microcapsules from optical microscopic observations; d_1 is density of the core material; d_2 is density of the coat material; p is the proportion of medicament in the microcapsules. All the test samples were examined for three times.

**In vitro drug release studies of microcapsule formulations**

In vitro drug release study was carried out in USP Electro Lab dissolution test apparatus using simulated gastric fluid as dissolution medium (900 mL phosphate buffer, pH 3.2, at 37 ±1°C, 100 rpm). An aliquot sample (5 mL) was withdrawn at an interval of 1 hr with replacement of fresh medium and analyzed for ampicillin content by UV-visible spectrophotometer at 320 nm (10, 11). All the experimental units were evaluated in triplicate (n=3). The same method was adopted for each batch of microcapsules.

**Infrared spectroscopy (IR)**

A Fourier Transformed Infrared Spectrophotometer (8400s, Shimadzu, Japan) was used to scan the drug samples prepared as KBr pellets, over the range of 4000-600 cm\(^{-1}\).

**Scanning Electron Microscopy (SEM)**

The SEM analysis was carried out using a scanning electron microscope (LEO, 435 VP, U.K.). Prior to examination, samples were mounted on an aluminium stub using a double sided adhesive tape and making it electrically conductive by coating with a thin layer of gold (approximately 20 nm) in vacuum. The scanning electron microscope was operated at an acceleration voltage of 05 KV.

**Drug content uniformity**

Initially, the formulations were tested for homogeneity by visual inspection. To ensure the homogeneity of drug content in the formulation of the tablet, six tubes were sampled from the different locations of the mixer and assayed for the drug content as stated above. Studies were performed in triplicate for all the formulations.

**RESULTS AND DISCUSSION**

All the microcapsules were found to be discrete, spherical and free flowing. The size could be separated and more uniform size of capsules could rapidly be obtained. The formulation of microcapsules has been presented in table 1. The trinocular microscopy (Figure 1) revealed that all obtained microcapsules were opaque, discrete and spherical particles with smooth surfaces, which further confirmed by SEM studies. distribution of selected microcapsules and the mean particle size for all formulations were graphically represented in figures 3. The mean diameter of the microcapsules was found to be increased with increase in proportion of coat material as shown in table 1. The particle size distribution was found as wide in formulation F3. So care must be taken during preparation of microcapsules that is stirring must be done with much high speed, there must be gradual reduction of temperature during cooling and avoidance of sticking of microcapsules. The flow properties and wall thickness of the microcapsules were shown in table 1. All the formulations had excellent flow properties. The highest wall thickness (4.267 µm) belonged to F3. The wall thickness of the microcapsules mainly depended on polymer content. As usual, the wall thickness of the microcapsules increased with polymer ratio as depicted in table 1. Relatively high drug content and encapsulation efficiency were observed for each formulation presented in table 1. The increased encapsulation efficiency may be attributed to the hydrophobic nature of ethyl cellulose and ampicillin. It was found that the encapsulation efficiency improved by decreasing the polymer content. The release of drug from various formulations was from 12 hrs and more as shown in figure 2. Drug releases from the microcapsules were studied in phosphate buffer pH 7.4 for a period 12 hrs. Drug release from the microcapsules (F1 and F2) was 94-97 % in first 6 hours, with the initial burst of nearly 50% within one hour (Table 2). Drug release from microcapsules (F1 and F3) sustained the drug release up-to 12 hours. The interaction between the drug and the carrier often leads to identifiable changes in the FT-IR profile of solid systems. FT-IR spectra at 45 scan and at a resolution of 1 cm\(^{-1}\) were recorded in KBr press pellets for pure drug (Figure 5A), polymer (Ethyl cellulose) (Figure 5B) and the selected (F3) microcapsule formulation (Figure 5C) of 1:4 drug / polymer ratios. In FT-IR studies, the characteristic C-N stretching at around 1620 cm\(^{-1}\) was clearly distinguishable in the selected formulation (F3). Additionally characteristics O-H stretching vibration at around 3250 cm\(^{-1}\) and N=O symmetrical and asymmetrical stretching at around 1560 and 1350 cm\(^{-1}\) respectively, were also observed.

The morphology of the ethyl cellulose ampicillin systems prepared by thermal change method was investigated by SEM analysis (Figure 2). Microcapsules appear as small spherical particle with smooth surfaces of homogenous morphology.

CONCLUSION

In conclusion, F3, containing drug: polymer ratio 1:4, was selected as the best microcapsule. Formulation because of its slower release rate, higher entrapment efficiency and excellent flow property. F3 (containing 1% w/w of drug loaded microcapsules and 0.6% w/w of ethyl cellulose) was found to be the best because releasing almost 100% of ampicillin over a period of 36 h in simulated gastric fluid, successfully. The novel formulation design facilitated the optimization and successful development of microcapsule. It was concluded that the applied protocol can be an effective strategy for the development of safe, easy, reproducible and cost effective oral delivery systems.
